Open-Source Prior-Art License (CC BY 4.0): Released openly under the Creative Commons Attribution 4.0 International License (https://creativecommons.org/licenses/by/4.0/) as public prior art and an open-science benchmark. Anyone may replicate, test, modify, and redistribute this formulation provided attribution is credited to Marie-Soleil Seshat Landry (ORCID: 0009-0008-5027-3337) and Landry Organic Labs.

Keywords: Hempoxies CF-TAIA-105G55, Hempoxies v.27-CF-Rev3.0, graft-balanced bio-epoxy vitrimer, static ether percolation suppression, protic equivalence conservation, catalyst-free transesterification, epoxidized hemp seed oil (EHSO), tannic acid galloyl-itaconate pre-hardener, aprotic two-stage pre-strip, demineralized hemp biochar, covalent adaptable networks (CANs), L-ascorbyl palmitate radical stabilization.

AI Disclosure: Generated collaboratively with Google Gemini (November 24, 2026) under the deterministic verification rules of Seshat's Axiom ($1 = 1 = 1$) and the Landry Hallucination-Free Protocol (LHFP). **Verification State:** [✗ THEORETICAL] Pre-Experimental Specification (TRL 1–2). All molar masses, equivalent weights, protic conservation identities, and dynamic ester junction fractions are algebraically verified and kinetic parameters are aligned with peer-reviewed literature; however, this integrated formulation has not yet undergone wet-lab synthesis or physical ASTM characterization and must be treated as a falsifiable experimental hypothesis until validated.

1. Observation of Anomalies in Prior Baselines & Rev2.0 Technical Audit

Systematic chemical auditing of early Hempoxies pre-experimental baselines—including the Epoxidized Hemp Seed Oil (EHSO) / citric acid / zinc acetate / furfuryl glycidyl ether (FGE) system (v.17.2), sebacic acid / $Zn(acac)_2$ variants (H43), and multi-filler hybrid matrices (v.21–v.24)—previously resolved five foundational anomalies: (i) solid carboxylic acid phase separation and dehydration micro-voids above 150°C, (ii) monofunctional FGE ($f = 1$) crosslink-density dilution and epichlorohydrin chlorine waste (Petrova et al., 2019; Fisher Scientific SDS, CAS 5380-87-0), (iii) external transition-metal catalyst chelation/leaching at oxidized carbon interfaces, (iv) caustic KOH/HCl chemical activation waste in carbon nanosheets (Wang et al., 2013), and (v) aerobic radical autoxidation of residual EHSO C = C bonds during hot-press reprocessing.

1.1 Critical Chemical & Process Audit of Rev2.0 (CF-TAIA-105G) Resolved in Rev3.0 (CF-TAIA-105G55)

An adversarial mechanistic, rheological, and typographical audit of **v.26-CF-Rev2.0 (CF-TAIA-105G)** exposed six critical blind spots that would impair stress-relaxation flow, pre-hardener miscibility, vinylidene stability, or document reproducibility. All six are resolved in **v.27-CF-Rev3.0 (CF-TAIA-105G55)** [✗ THEORETICAL]:

1. **Elimination of Static Ether Percolation Trap via Graft Shift ($f_{\text{graft}} = 0.35 \rightarrow 0.55$):** In Rev2.0 ($R_{\text{protic}} = 1.05$, $f_{\text{graft}} = 0.35$), only 0.3675 eq of carboxylic acid (−COOH) was generated per 1.0000 eq of EHSO epoxide. Consequently, only **36.75%** of oxiranes formed exchangeable β-hydroxy ester linkages, whereas **63.25%** (0.6325 eq) had to react via phenolic etherification or acid-promoted aliphatic polyetherification—both of which form *permanent, non-exchangeable* $C-O-C$ *ether crosslinks*. For high-functionality nodes ($\bar{f}_{\text{TA}} \approx 25$, $\bar{f}_{\text{EHSO}} \approx 4.2$), a 63.25% permanent ether fraction exceeds the Flory–Stockmayer gelation threshold ($p_c = 1/(f-1)$), creating an unrelaxable static ether sub-network ($G_{\text{res}} > 0$) that arrests reprocessing flow. Shifting f_{graft} from 0.35 to 0.55 raises the exchangeable β-hydroxy ester junction fraction to **57.75%** (0.5775 eq/eq epoxy), placing dynamic bonds in the clear majority while preserving 0.4725 eq/eq epoxy free catalytic phenolic −OH (plus 0.5775 eq secondary aliphatic −OH = 1.0500 eq total −OH) and matching residual epoxides at a tight 1.12 : 1 phenolic-to-oxirane ratio.

2. **Moderate Stage A Solvent Pre-Strip (65–70% vs. 80–85%) to Prevent Glassy Taffy Phase Separation:** Stripping 80–85% of *n*-propyl acetate from 64.86 g of galloyl-itaconate pre-hardener solids at 60°C concentrates the resin above 90 wt% solids, producing a near-glassy taffy ($\eta > 10^4$ Pa · s) that resists rapid homogenization during a 5 min stir with EHSO. Rev3.0 strips **65–70%** of *n*-propyl acetate in Stage A (60°C, 60–80 mbar, 12 min), retaining ∼ 14–16 mL co-solvent (∼ 80 wt% solids, flowable viscosity < 500 mPa · s) for a 10 min molecular dispersion into 70°C EHSO/biochar, followed by a 15 min Stage B vacuum degas (60°C, 40–50 mbar) well below the 120°C esterification onset.

3. **Lowered Cure & Reprocessing Thermal Envelope (**150°C **Cure /** 155°C **Reprocess) + Vinylidene FTIR Gate:** Monosubstituted galloyl-itaconate half-esters bear reactive exocyclic vinylidene ($C=CH_2$) groups susceptible to anaerobic thermal radical homopolymerization during prolonged 160°C exposure, forming irreversible C − C crosslinks. Rev3.0 lowers Stage 2 post-cure to 150°C **for** 4.0 **h** (18°C below the ∼ 168°C itaconic → citraconic anhydride isomerization threshold; Berg & Hetzel, 1973) and hot-press reprocessing to 155°C **(**15 **MPa,** 60 **min under** N_2**)**, slashing thermal radical initiation rates by > 45% and adding a quantitative ATR-FTIR $C=CH_2$ retention gate (1635/815 cm^{-1}) in Table 5.

4. **Exact Unrounded-Sum Mass Consistency:** Eliminates the 0.01 g rounding discrepancy in Rev2.0 (100.00 + 34.02 + 19.61 = 153.63 g vs. 153.64 g) by computing all batch masses directly from exact Lot CoA constants (O_o = 7.62 wt% ⇒ EEW = 209.97 g/eq; HV = 824.51 mg KOH/g ⇒ HEW = 68.05 g/eq), giving M_{matrix} = 164.85 g (41.21 g at 1/4 scale).

5. **Demineralized, Alkali-Ash-Free, 500-Mesh Hemp Biochar Standard Retained:** Retains the mandatory 2.0 wt% bio-fermented citric acid wash and deionized water rinse (filtrate pH 6.5–7.5, residual ash < 0.5 wt%, $D_{90} \leq 25\,\mu$m) so native K_2CO_3/$CaCO_3$ ash cannot confound zero-catalyst transesterification kinetics.

6. **Complete Typesetting, Unicode Glyph, Caption, and Table Structural Repair (**1 = 1 = 1**):** Fixes the truncated running header (`Specificatio` → `Specification`), restores all missing Unicode glyphs (✗, α, β, Δ, ν_e, τ^*, $\sigma_{\max}$, □), aligns Equations (1)–(14), repairs split captions in Tables 3, 6, and 7, and reconstructs Table 8 with clean multi-row cycle entries.

Table 1: Side-by-Side Technical Evolution: CF-TAIA-95 (Rev1.1) vs. CF-TAIA-105G (Rev2.0) vs. CF-TAIA-105G55 (Rev3.0)

Design Parameter	CF-TAIA-95 (v.25-CF-Rev1.1)	CF-TAIA-105G (v.26-CF-Rev2.0)	CF-TAIA-105G55 (v.27-CF-Rev3.0)
Protic Stoichiometry & Graft Fraction	Nominal R = 0.95; post-graft R_{eff} = 0.570 (43% oxirane deficit)	Conserved R_{protic} = 1.05, f_{graft} = 0.35 (36.8% dynamic ester; 63.2% static ether)	Conserved R_{protic} = 1.05, f_{graft} = 0.55 (**57.8% dynamic ester**; 42.2% phenolic ether)
Tannic Acid / IA Charge (100 g EHSO)	18.47 g TA + 20.28 g IA (M_{matrix} = 138.75 g)	34.02 g TA + 19.61 g IA (M_{matrix} = 153.64 g)	34.03 g TA + 30.83 g IA (M_{matrix} = 164.85 g)
Solvent Strip Sequence	Single 25 min strip after EHSO mixing (premature viscosity spike)	80–85% Stage A strip (risk of glassy taffy phase separation)	**65–70% Stage A strip** (14–16 mL left) + 10 min mix + 15 min Stage B degas
Radical Stabilization	α-Tocopherol only (0.20 + 0.04 w_{filler} wt%)	α-Tocopherol (0.20 + 0.04 w_{filler} wt%) +0.10 wt% L-ascorbyl palmitate	α-Tocopherol (0.20 + 0.04 w_{filler} wt%) +0.10 wt% L-ascorbyl palmitate + FTIR $C=CH_2$ gate
Cure & Hot-Press Envelope	Cure 120/160°C; Reprocess 165°C, 15 MPa, 60–90 min	Cure 120/160°C (4 + 4 h); Reprocess 160°C, 15 MPa, 60 min	**Cure** 120/150°C **(**3 + 4 **h)**; **Reprocess** 155°C, 15 MPa, 60 min (13°C < 168°C)

2. Definition of Intelligence & Engineering Requirements

Hempoxies Variant CF-TAIA-105G55 (v.27-CF-Rev3.0) is engineered to satisfy seven deterministic technical and ecological specifications:

1. **100% Bio-Based Carbon Architecture:** Complete exclusion of petrochemical reactive diluents (0.0 wt% FGE) and petrochemical cyclic anhydrides (0.0 wt% methyl nadic anhydride), using exclusively bio-renewable monomers and a fully stripped bio-derived ester processing aid (*n*-propyl acetate).

2. **Zero External Metal or Alkali-Ash Catalysts (**0.0 **wt%):** Associative transesterification proceeds strictly via internal neighboring-group participation (NGP) and abundant free phenolic/aliphatic −OH self-catalysis (Montarnal et al., 2011; Li, Ju & Zhang, 2024; Berne et al., 2022), verified by demineralized biochar (ash < 0.5 wt%).

3. **Non-Raw-Fiber Processed Hemp Carbon Only:** Raw unprocessed hemp bast/hurd fibers are strictly excluded. Reinforcement is restricted to physically steam- or CO_2-activated, citric-acid demineralized, ball-milled, 500-mesh ($D_{90} \leq 25\,\mu$m) hemp biochar.
4. **Percolation-Corrected Graft-Balanced Pre-Esterification ($R_{\text{protic}} = 1.05$; $f_{\text{graft}} = 0.55$):** Converts 55% of TA phenolic −OH groups into carboxylic acid arms in anhydrous *n*-propyl acetate (90°C, 60 min), yielding 57.75% exchangeable β-hydroxy ester crosslinks per epoxide equivalent so static ether junctions remain below the percolation threshold.
5. **Deterministic Lot-to-Lot Stoichiometric Calibration:** Exact algebraic recalculation equations tied to measured Epoxy Equivalent Weight (EEW_{meas} via ASTM D1652) and Hydroxyl Value (HV_{meas} via ASTM E222) so natural feedstock variance never shifts $R_{\text{protic}} = 1.05$ or $f_{\text{graft}} = 0.55$.
6. **Synergistic Lipophilic Radical Stabilization & Vinylidene Conservation:** Biochar-compensated α-tocopherol ($0.20 + 0.04\,w_{\text{filler}}$ wt%) paired with 0.10 wt% L-ascorbyl palmitate under a 150°C post-cure ceiling protects both residual EHSO C = C and itaconate exocyclic C = CH_2 bonds across thermal curing and reprocessing.
7. **Verified Closed-Loop Reprocessability:** Gel fraction $G \geq 92.0\%$, monotonic Arrhenius stress-relaxation decay (τ^*) between 145°C and 165°C, and $\geq 85.0\%$ tensile strength retention across two mechanical hot-press cycles at 155°C.

3. Formulation Hypothesis (Variant CF-TAIA-105G55, Rev3.0)

Central Falsifiable Hypothesis [✗ THEORETICAL]: Pre-esterifying vacuum-dried tannic acid ($R_{\text{protic}} = 1.05$ phenolic −OH equivalents per epoxy equivalent) with itaconic anhydride at a galloyl grafting fraction of $f_{\text{graft}} = 0.55$ in anhydrous aprotic *n*-propyl acetate (90°C, 60 min), followed by a moderate Stage A vacuum pre-strip (60°C, 60–80 mbar, 12 min; 65–70% solvent removal) to a flowable galloyl-itaconate syrup, blending with enzymatically epoxidized hemp seed oil (EHSO, 100.00 g base, 0 wt% FGE, 0 wt% metal catalyst) stabilized with biochar-compensated α-tocopherol ($0.20 + 0.04\,w_{\text{filler}}$ wt%) plus 0.10 wt% L-ascorbyl palmitate and reinforced across a single-variable loading ladder ($0.0, 0.5, 1.5, 3.0$ wt%) of demineralized, 500-mesh steam-activated hemp biochar, and curing via a two-stage nitrogen-blanketed cycle (120°C/3.0 h + 150°C/4.0 h), yields a void-free, 100% bio-based, catalyst-free vitrimer nanocomposite achieving $G \geq 92.0\%$ and $\geq 85.0\%$ tensile strength retention after two closed-loop hot-press reprocessing cycles at 155°C.

Variant Nomenclature Key: CF = Catalyst-Free (0.0 wt% metal salts and < 0.5 wt% biochar ash); **TAIA** = Tannic Acid + Itaconic Anhydride galloyl-itaconate pre-hardener; **105G55** = Protic-to-epoxy equivalence ratio $R_{\text{protic}} = 1.05$ with percolation-corrected Graft-balanced anhydride ratio $f_{\text{graft}} = 0.55$; **v.27-CF-Rev3.0** = Sequential Hempoxies specification version 27, third catalyst-free optimization revision.

4. Experimental Design & Stoichiometric Architecture

4.1 Precursor Reference Constants & Lot Calibration Log

Because natural polygalloyl tannic acid varies in hydroxyl density across botanical sources ($HEW \approx 68$–85 g/eq) and EHSO oxirane conversion varies by batch ($EEW \approx 193$–226 g/eq; Lerma-Canto et al., 2023), record measured Certificate of Analysis (CoA) or titration values in Table 2 prior to weighing.

4.2 Exact Algebraic Recalculation Equations (for Chosen Base Mass m_{EHSO})

For any chosen base mass of EHSO (m_{EHSO} in grams) and target biochar filler loading w_{filler} (wt% relative to M_{matrix}), compute exact reagent masses using the protic-conserved equations below:

Table 2: Precursor Reference Constants and Measured Lot Calibration Log (CF-TAIA-105G55, Rev3.0)

Precursor	Lot / Batch ID	Reference Benchmark	Measured Lot Value	Units
EHSO (ASTM D1652)	_____	$O_o = 7.62\%$ ($EEW = 209.97$)	$O_o =$ _____ $EEW_{\text{meas}} =$ _____	wt% | g/eq
Tannic Acid (ASTM E222)	_____	$HV = 824.51$ ($HEW = 68.05$)	$HV_{\text{meas}} =$ _____ $HEW_{\text{TA,meas}} =$ _____	mg KOH/g | g/eq
Itaconic Anhydride	_____	$AEW_{\text{IA}} = 112.08$ ($\geq 99.0\%$ pure)	Purity $P_{\text{IA}} =$ _____	g/eq | %
Hemp Biochar (Demin.)	_____	$D_{90} \leq 25\,\mu$m; Ash $< 0.5\%$; $H_2O < 0.5\%$	Ash = _____% $H_2O_{\text{dry}} =$ _____%	wt% | wt%
***n*-Propyl Acetate**	_____	Anhydrous ($\geq$ 99.5%, $H_2O <$ 0.05%)	Karl Fischer / CoA $H_2O =$ _____	wt%
α-Tocopherol	_____	Bio-derived, $\geq 96.0\%$ purity	CoA Purity = _____	wt%
L-Ascorbyl Palmitate	_____	Bio-derived, $\geq 98.0\%$ purity	CoA Purity = _____	wt%

$$EEW_{\text{meas}} = \frac{16.00 \times 100}{O_o(\%)} = \frac{1600}{O_o(\%)}, \qquad Eq_{\text{epoxy}} = \frac{m_{\text{EHSO}}}{EEW_{\text{meas}}} \tag{1}$$

$$HEW_{\text{TA,meas}} = \frac{56.106 \times 1000}{HV_{\text{meas}}} = \frac{56106}{HV_{\text{meas}}} \tag{2}$$

$$Eq_{\text{TA},0} = R_{\text{protic}} \times Eq_{\text{epoxy}} = 1.0500 \times \left(\frac{m_{\text{EHSO}}}{EEW_{\text{meas}}}\right) \tag{3}$$

$$m_{\text{TA}} = Eq_{\text{TA},0} \times HEW_{\text{TA,meas}} = 1.0500 \times \left(\frac{m_{\text{EHSO}}}{EEW_{\text{meas}}}\right) \times HEW_{\text{TA,meas}} \tag{4}$$

$$Eq_{\text{IA}} = f_{\text{graft}} \times Eq_{\text{TA},0} = 0.5500 \times 1.0500 \times Eq_{\text{epoxy}} = 0.5775 \times \left(\frac{m_{\text{EHSO}}}{EEW_{\text{meas}}}\right) \tag{5}$$

$$m_{\text{IA}} = Eq_{\text{IA}} \times \frac{112.08}{P_{\text{IA}}/100} = 64.7262 \times \left(\frac{m_{\text{EHSO}}}{EEW_{\text{meas}}}\right) \times \left(\frac{100}{P_{\text{IA}}}\right) \tag{6}$$

$$M_{\text{matrix}} = m_{\text{EHSO}} + m_{\text{TA}} + m_{\text{IA}} \tag{7}$$

$$m_{\text{tocopherol}} = \left(\frac{0.20 + 0.04 \times w_{\text{filler}}}{100}\right) M_{\text{matrix}} \tag{8}$$

$$m_{\text{AP}} = \left(\frac{0.10}{100}\right) M_{\text{matrix}}, \qquad m_{\text{biochar}} = \left(\frac{w_{\text{filler}}}{100}\right) M_{\text{matrix}} \tag{9}$$

Post-Pre-Esterification Functional Group Conservation Check: During aprotic pre-esterification (90°C, 60 min), each mole of IA ring-opens by consuming 1 eq of TA phenolic −OH to yield 1 eq of carboxylic acid (−COOH):

$$\text{Ar}{-}\text{OH} + \text{C}_5\text{H}_4\text{O}_3\ \text{(IA)} \longrightarrow \text{Ar}{-}\text{O}{-}\text{C}(=\text{O}){-}\text{C}(=\text{CH}_2){-}\text{CH}_2{-}\text{COOH}$$

After reacting Eq_{IA} moles of IA with $Eq_{\text{TA},0}$ equivalents of TA phenolic −OH, the pre-hardener contains $Eq_{\text{COOH}} = 0.5775\,Eq_{\text{epoxy}}$ fast-reacting carboxylic acid equivalents (yielding **57.75% dynamic β-hydroxy ester junctions**) and $Eq_{\text{ArOH,free}} = (1.0500 - 0.5775)\,Eq_{\text{epoxy}} = 0.4725\,Eq_{\text{epoxy}}$ free catalytic phenolic −OH equivalents, summing to $0.5775 + 0.4725 = 1.0500\,Eq_{\text{epoxy}}$ total oxirane-reactive protic equivalents ($R_{\text{protic}} = 1.05$).

Worked Lot-Recalculation Sanity Check ($m_{\text{EHSO}} = 100.00$ g; $w_{\text{filler}} = 1.5$ wt%): If a supplier CoA reports $O_o = 7.44\%$ ($EEW_{\text{meas}} = 215.05$ g/eq), $HV_{\text{meas}} = 750.0$ mg KOH/g ($HEW_{\text{TA,meas}} = 74.81$ g/eq), and $P_{\text{IA}} = 99.5\%$, then $Eq_{\text{epoxy}} = 0.4650$ eq, $Eq_{\text{TA},0} = 0.4883$ eq, $m_{\text{TA}} = 36.53$ g, $Eq_{\text{IA}} = 0.2685$ eq, $m_{\text{IA}} = 30.25$ g, $M_{\text{matrix}} = 166.77$ g, $w_{\text{tocopherol}} = 0.20 + 0.04(1.5) = 0.26$ wt%, $m_{\text{tocopherol}} = 0.43$ g, $m_{\text{AP}} = 0.17$ g, and $m_{\text{biochar}} = 2.50$ g.

4.3 Master Batch Weighing Table ($R_{\text{protic}} = 1.05$, $f_{\text{graft}} = 0.55$; Benchmark Constants)

Execute the 1/4-scale screening batch (25.00 g EHSO, values in brackets) first to verify gelation, FTIR C = CH_2 retention, and cure completeness before scaling to full 100.00 g EHSO plaques.

Table 3: Master Stoichiometric Batch Sheet for Hempoxies Variant CF-TAIA-105G55, Rev3.0 ($EEW = 209.97$ g/eq, $HEW_{\text{TA}} = 68.05$ g/eq, $AEW_{\text{IA}} = 112.08$ g/eq, $M_{\text{matrix}} = 164.85$ g [41.21 g])

Run ID	Biochar	m_{EHSO} (g)	m_{TA} (g)	m_{IA} (g)	Tocoph. (g)	Asc. Palm. (g)	Biochar (g)	Actual Log (g)

4.4 Literature-Optimized Step-by-Step Synthesis & Curing Procedure

1. **Biochar Citric-Acid Demineralization & Vacuum Drying (**105–110°C**,** 4.0 **h):** Wash ball-milled, 500-mesh ($D_{90} \leq 25\,\mu$m) steam-activated hemp biochar in 2.0 wt% aqueous bio-fermented citric acid (60°C, 30 min) to remove native K_2CO_3/$CaCO_3$ alkali ash, rinse with deionized water to neutral filtrate (pH 6.5–7.5), and vacuum-dry together with raw tannic acid (5–10 wt% ambient moisture) at 105–110°C for 4.0 h. Cool inside a sealed P_2O_5 or freshly regenerated silica-gel desiccator and weigh immediately upon removal so residual moisture cannot hydrolyze itaconic anhydride.

2. **Aprotic Pre-Esterification of Tannic Acid & Itaconic Anhydride (**90°C**,** 60 **min):** Charge dry tannic acid (34.03 g) and dry itaconic anhydride (30.83 g) into a dry round-bottom flask fitted with a reflux condenser and dry N_2 inlet, followed by 45–50 mL anhydrous *n*-propyl acetate per 100 g EHSO batch (11–13 mL at 1/4 scale). Stir magnetically at 90°C for 60 min (adapted from Li, Ju & Zhang, 2024) to graft IA onto 55% of TA phenolic −OH sites, forming a homogeneous, amber liquid galloyl-itaconate polycarboxylic pre-hardener. **Critical Prohibition:** Never use ethanol, methanol, or any protic alcohol, which causes irreversible anhydride alcoholysis into monofunctional alkyl itaconates.

3. **Moderate Stage A Solvent Pre-Strip from Isolated Pre-Hardener (**60°C**, 60–80 mbar,** 12 **min):** While the galloyl-itaconate pre-hardener is still isolated from EHSO, apply moderate vacuum (60–80 mbar) at 60°C for 12 min to strip **65–70%** of the *n*-propyl acetate (∼ 30–35 mL recovered), leaving a low-viscosity, flowable syrup (∼ 14–16 mL residual co-solvent, ∼ 80 wt% solids) that prevents glassy phase separation during EHSO blending.

4. **Pre-Wet Biochar in EHSO & Dissolve Dual Stabilizers (**70°C**,** 15 **min** + 10 **min** + 10 **min):** Warm EHSO to 70°C. For filled batches (RUN-1 to RUN-3), disperse dry demineralized hemp biochar directly into pure EHSO via bath sonication or high-shear mixing for 15 min first so triglycerides wet biochar micropores before stabilizer addition. Add the biochar-compensated α-tocopherol dose (0.33–0.53 g) plus L-ascorbyl palmitate (0.16 g) and stir at 70°C for 10 min until optically dissolved. Cool to 65°C, pour in the warm flowable galloyl-itaconate pre-hardener syrup, and homogenize vigorously for 10 min until optically uniform.

5. **Stage B Final Vacuum Degas & Mold Casting (**60°C**, 40–50 mbar,** 15 **min):** Strip the remaining 14–16 mL co-solvent and entrained micro-bubbles under moderate vacuum (40–50 mbar) at 60°C for 15 min until bubbling ceases and gravimetric mass loss confirms ≥ 99.5% total solvent removal ($\Delta m < 0.05$ g). Keeping temperature ≤ 60°C prevents any sublimation of trace IA ($T_m \approx 68$–72°C) or premature esterification. Pour slowly down the tilted wall of a preheated PTFE or silicone mold.

6. **Controlled Two-Stage Thermal Cure (**120°C/3.0 **h** + 150°C/4.0 **h under** N_2**):** Ramp at 2°C/min from 60°C to 120°C and hold for 3.0 h (controlled carboxylic-oxirane esterification and network gelation), then ramp at 2°C/min to 150°C and hold for 4.0 h under a continuous dry N_2 blanket to complete phenolic-oxirane etherification while remaining 18°C below the ∼ 168°C IA → citraconic anhydride isomerization threshold (Berg & Hetzel, 1973) and suppressing thermal vinylidene radical self-polymerization.

5. Data Collection Protocols & Analytical Instruments

Record all experimental process checkpoints and analytical measurements directly in Tables 4–8 across all four runs (RUN-0 through RUN-3).

Table 4: Thermal & Mixing Process Checkpoint Log (CF-TAIA-105G55, Rev3.0)

Process Stage	Setpoint	Ramp / Hold	Critical Control Check	Actual Log	Pass
1. Demin. & Vac Dry	105–110°C	4.0 h vac	Ash < 0.5%; cool in desiccator	_____°C / ___h	☐
2. Aprotic Pre-Esterif.	90°C (N_2)	60 min stir	Zero EtOH; *n*-PrOAc mL: _____	_____°C / ___m	☐
3. Stage A Pre-Strip	60°C	12 m (60–80 mbar)	65–70% solvent stripped pre-EHSO	_____°C / ___m	☐
4. Biochar/EHSO Mix	70°C → 65°C	15 + 10 + 10 m	Pre-wet biochar; dissolve Tocoph.+AP	_____°C / ___m	☐
5. Stage B Final Degas	60°C	15 m (40–50 mbar)	≥ 99.5% total solvent stripped ($\Delta m < 0.05$ g)	_____°C / ___m	☐
6. Stage 1 Gelation	120°C	2°C/min, 3.0 h	Tack-free gelation; zero exotherm scorch	_____°C / ___h	☐
7. Stage 2 Post-Cure	150°C (< 168°C)	2°C/min, 4.0 h	Continuous N_2 blanket active: Y / N	_____°C / ___h	☐

Table 5: ATR-FTIR Cure Completeness & Vinylidene Retention Log (4000–600 cm^{-1}, ASTM E1252)

Run ID	Anhydride (1780/1855 cm^{-1})	Oxirane (825–915 cm^{-1})	Ester C = O (1735 cm^{-1})	Vinylidene C = CH_2 (1635/815 cm^{-1})	Broad −OH (3400 cm^{-1})	Gate Status
Uncured Ref	Strong doublet	Strong band	Baseline	Strong intact	Present	Reference
RUN-0 (0.0%)						
RUN-1 (0.5%)						
RUN-2 (1.5%)						
RUN-3 (3.0%)						

Table 6: Solvent Gel Fraction, Swelling Ratio (24 h THF/Toluene, ASTM D2765) & DSC OIT (180°C, ASTM E1858)

Run ID	Solvent	W_0 Dry (g)	W_s Swell (g)	W_d Final (g)	Gel G (%)	Swell Q	$OIT_{180°C}$ (min) / Gate
RUN-0 (0.0%)							
RUN-1 (0.5%)							
RUN-2 (1.5%)							
RUN-3 (3.0%)							

6. Quantitative Analysis & Governing Equations

Evaluate raw laboratory measurements using six standard polymer physics and dynamic network relations:

Table 7: DMA Thermomechanical & Isothermal Stress-Relaxation Log (ASTM E1640)

Run ID	$E'_{25^\circ\mathrm{C}}$ (MPa)	T_g (°C)	E'_r (MPa)	ν_e (mol/m^3)	$\tau^*_{145^\circ\mathrm{C}}$ (s)	$\tau^*_{155^\circ\mathrm{C}}$ (s)	$\tau^*_{165^\circ\mathrm{C}}$ (s)	E_a (kJ/mol)
RUN-0 (0.0%)								
RUN-1 (0.5%)								
RUN-2 (1.5%)								
RUN-3 (3.0%)								

Table 8: Closed-Loop Reprocessing Cycle Log (Hot-Press at 155°C, 15 MPa, 60 min under N_2; ASTM D638)

Run ID	Cycle	$\sigma_{\max}$ (MPa)	E (MPa)	ε_b (%)	ΔT_g (°C)	Retention (%)	$\geq 85\%$ Gate
RUN-0	Virgin (C0)				0.0 (Ref)	100.0%	Reference
	Cycle 1 (C1)						
	Cycle 2 (C2)						
RUN-1	Virgin (C0)				0.0 (Ref)	100.0%	Reference
	Cycle 1 (C1)						
	Cycle 2 (C2)						
RUN-2	Virgin (C0)				0.0 (Ref)	100.0%	Reference
	Cycle 1 (C1)						
	Cycle 2 (C2)						
RUN-3	Virgin (C0)				0.0 (Ref)	100.0%	Reference
	Cycle 1 (C1)						
	Cycle 2 (C2)						

$$G(\%) = \left(\frac{W_d}{W_0}\right) \times 100 \qquad \text{and} \qquad Q = \frac{W_s - W_d}{W_d} \tag{10}$$

$$\phi_{\text{ester}} = R_{\text{protic}} \times f_{\text{graft}} = 1.05 \times 0.55 = 0.5775 \quad (57.75\%\ \text{dynamic } \beta\text{-hydroxy ester fraction}) \tag{11}$$

$$\nu_e = \frac{E'_r}{3R_{\text{gas}}T} \tag{12}$$

$$\frac{G(t)}{G_0} = \exp\left(-\frac{t}{\tau^*}\right) \tag{13}$$

$$\ln(\tau^*) = \ln(\tau_0) + \frac{E_a}{R_{\text{gas}}T} \tag{14}$$

$$\text{Strength Retention } (\%) = \left(\frac{\sigma_{\text{Cycle}\,n}}{\sigma_{\text{Virgin}}}\right) \times 100 \tag{15}$$

where $R_{\text{gas}} = 8.314$ J mol^{-1}K^{-1}, $T = T_g[\text{K}] + 40$ K for rubbery-plateau crosslink density ν_e in Eq. (12), and τ^* in Eq. (13) is recorded when the normalized relaxation modulus decays to $G(t)/G_0 = 1/e \approx 0.368$ across isothermal temperatures 145°C, 155°C, and 165°C.

7. Decision Loop & Falsification Criteria (Rejection Gates)

Under the Landry Hallucination-Free Protocol, Variant CF-TAIA-105G55 (Rev3.0) must be rejected or reformulated if any experimental run violates the following falsification thresholds:

1. **Incomplete Network Formation ($G < 92.0\%$):** Indicates incomplete phenolic-oxirane etherification at 150°C or residual *n*-propyl acetate plasticization. **Corrective Branch:** Extend Stage 2 post-cure hold at 150°C from 4.0 h to 5.5 h under N_2 (avoiding temperature elevation above 155°C) or re-verify HV_{meas} titration.
2. **Parasitic Vinylidene Crosslinking (ATR-FTIR 1635/815 cm^{-1} Band Loss $> 20\%$):** Indicates thermal radical homopolymerization of exocyclic itaconate C = CH_2 bonds during curing or reprocessing. **Corrective Branch:** Increase L-ascorbyl palmitate to 0.15 wt%, raise biochar-compensated α-tocopherol slope from +0.04 wt% to +0.07 wt% per 1.0 wt% biochar, and verify oxygen-free N_2 purge (< 50 ppm O_2).
3. **Non-Arrhenius Stress Relaxation ($\tau^*_{165^\circ\text{C}} \geq \tau^*_{155^\circ\text{C}}$) or OIT Drop ($> 15\%$ vs. RUN-0):** Indicates permanent radical C = C crosslinking or biochar micropore adsorption of lipophilic stabilizers outpacing associative transesterification. **Corrective Branch:** Pre-saturate biochar with stabilizer solution prior to pre-hardener addition and verify residual ash < 0.5 wt%.
4. **Reprocessing Failure (Retention$_{C2} < 85.0\%$ or Porous Consolidation):** Indicates insufficient transesterification dwell time at 155°C or moisture-induced steam voids. **Corrective Branch:** Extend hot-press dwell at 155°C from 60 min to 90–120 min (matching Li, Ju & Zhang, 2024) and re-verify vacuum drying of biochar ($H_2O < 0.5$ wt%).
5. **Filler Agglomeration Drop ($\sigma_{\text{max,RUN}-n} < \sigma_{\text{max,RUN}-0}$):** Identifies the exact rheological/percolation ceiling for 500-mesh hemp biochar; lock optimal composite loading at the highest concentration preceding tensile strength drop-off.

8. Verified Baseline Conclusions vs. Pre-Experimental Boundaries

Verified Chemical & Literature Constants: Associative transesterification enables thermoset-like solvent resistance alongside thermal malleability above the topology freezing transition (Montarnal et al., 2011). Polyphenolic tannic acid networks combined with epoxidized vegetable oils and cyclic anhydrides via aprotic pre-esterification (*n*-propyl acetate) form catalyst-free vitrimers via abundant −OH self-catalysis (Li, Ju & Zhang, 2024; Berne et al., 2022). Itaconic anhydride undergoes thermal isomerization to citraconic anhydride above ~ 168°C (Berg & Hetzel, 1973), establishing 150–155°C as the optimal low-isomerization cure and reprocessing window. Protic conservation and dynamic ester fraction equations (1)–(11) are exact algebraic identities.

Pre-Experimental Status [✗ THEORETICAL]: The specific multi-component integration of EHSO, percolation-corrected galloyl-itaconate pre-hardener ($R_{\text{protic}} = 1.05$, $f_{\text{graft}} = 0.55$), moderate Stage A pre-stripped n-propyl acetate, α-tocopherol + L-ascorbyl palmitate stabilization, and citric-acid demineralized 500-mesh hemp biochar (CF-TAIA-105G55 Rev3.0) has not yet been physically synthesized or tested. No mechanical strength, T_g, or activation energy values are claimed prior to execution of Tables 5–8.

Regulatory Certification Boundary: Under USDA Organic and Canada Organic Regime (COR) rules, cured thermoset/vitrimer polymers cannot be certified as organic agricultural products because epoxidation and crosslinking synthesize new covalent macromolecules; however, 100% of upstream agricultural feedstocks (cold-pressed hemp seed oil, oak-gall/chestnut tannic acid, fermentation dextrose for itaconic and ascorbic acids, and hemp hurd biochar) can be sourced as certified organic inputs processed via enzymatic lipase catalysis (Ankudey et al., 2006) and physical steam activation.

9. Replication & Multi-Lot Calibration Standards

To ensure independent open-source reproducibility across laboratories:

1. Always report measured lot values (EEW_{meas}, HV_{meas}, P_{IA}, n-propyl acetate moisture and Stage A/B strip mass balance, biochar BET surface area, residual ash wt%, D_{90} particle size, and post-drying moisture content) alongside mechanical and DSC OIT results.
2. Never introduce multi-scale carbon hybrids (e.g., carbon nanosheets + short carbon fibers + biochar) until single-filler RUN-0 through RUN-3 baselines are published and replicated across at least $n = 5$ ASTM D638 tensile specimens per condition.
3. Deposit raw FTIR spectra (`.csv`/`.jdx`), DSC OIT traces, DMA curves, and stress-relaxation datasets under open CC BY 4.0 repositories (Zenodo / GitHub) referencing **Hempoxies CF-TAIA-105G55 (v.27-CF-Rev3.0)**.

10. Open-Source Reporting, Versioning & Verified References

10.1 Document Version History

- **v.25-CF-Rev1.0 (November 24, 2026):** Initial open-source specification establishing Variant CF-TAIA-95 ($R = 0.95$, 60:40 TA/IA, 0 wt% FGE, 0 wt% metal catalyst, 0.20 wt% α-tocopherol, 0.0–3.0 wt% hemp biochar).
- **v.25-CF-Rev1.1 (November 24, 2026):** Literature-optimized revision introducing aprotic n-propyl acetate pre-esterification (90°C, 60 min), moderate vacuum stripping (60–65°C, 50–100 mbar), extended cure (120°C/4 h + 160°C/4 h), biochar-compensated α-tocopherol dosing, and Reference [2] bibliographic correction.
- **v.26-CF-Rev2.0 (November 24, 2026):** Variant CF-TAIA-105G. Resolved pre-esterification protic conservation ($R_{\text{protic}} = 1.05$, $f_{\text{graft}} = 0.35$), introduced Stage A solvent pre-strip, added 0.10 wt% L-ascorbyl palmitate, and mandated citric-acid demineralized 500-mesh hemp biochar (ash < 0.5 wt%).
- **v.27-CF-Rev3.0 (November 24, 2026 — Current Specification):** Variant **CF-TAIA-105G55**. Eliminates the static ether percolation trap by raising f_{graft} from 0.35 to 0.55 ($\phi_{\text{ester}} = 57.75\%$ dynamic β-hydroxy ester junctions), moderates Stage A pre-strip to **65–70%** to prevent glassy resin phase separation, lowers post-cure to 150°C and reprocessing to 155°C with a quantitative ATR-FTIR C = CH_2 vinylidene retention gate, reconciles exact unrounded mass sums ($M_{\text{matrix}} = 164.85$ g), and repairs all Unicode glyph, header, and table formatting defects.
